Matrix inverses

Left inverses

- ◆ a number x that satisfies $xa = 1$ is called the inverse of a
- ◆ inverse (i.e., $1/a$) exists if and only if $a \neq 0$, and is unique
- ◆ a matrix X that satisfies $XA = I$ is called a left inverse of A
- ◆ if a left inverse exists, we say that A is *left-invertible*
- ◆ example: the matrix

$$A = \begin{bmatrix} -3 & -4 \\ 4 & 6 \\ 1 & 1 \end{bmatrix}$$

has two different left inverses:

$$B = \frac{1}{9} \begin{bmatrix} -11 & -10 & 16 \\ 7 & 8 & -11 \end{bmatrix}, \quad C = \frac{1}{2} \begin{bmatrix} 0 & -1 & 6 \\ 0 & 1 & -4 \end{bmatrix}$$

Matrix inverses

Left inverse and column independence

◆ if A has a left inverse C then the columns of A are linearly independent

◆ to see this: if $Ax = 0$ and $CA = I$ then

$$0 = C 0 = C (Ax) = (CA) x = Ix = x$$

◆ the converse is also true, so

a matrix is left-invertible if and only if its columns are linearly independent

◆ matrix generalization of

a number is invertible if and only if it is nonzero

◆ so left-invertible matrices are tall or square

Matrix inverses

Solving linear equations with a left inverse

- ◆ suppose $A\mathbf{x} = \mathbf{b}$, and A has a left inverse C
- ◆ then $C\mathbf{b} = C(A\mathbf{x}) = (CA)\mathbf{x} = I\mathbf{x} = \mathbf{x}$
- ◆ so multiplying the right-hand side by a left inverse yields the solution

Matrix inverses

Example

$$A = \begin{bmatrix} -3 & -4 \\ 4 & 6 \\ 1 & 1 \end{bmatrix}, \quad b = \begin{bmatrix} 1 \\ -2 \\ 0 \end{bmatrix}$$

- ◆ over-determined equations $Ax = b$ have (unique) solution $x = (1, -1)$
- ◆ A has two different left inverses

$$B = \frac{1}{9} \begin{bmatrix} -11 & -10 & 16 \\ 7 & 8 & -11 \end{bmatrix}, \quad C = \frac{1}{2} \begin{bmatrix} 0 & -1 & 6 \\ 0 & 1 & -4 \end{bmatrix}$$

- ◆ multiplying the right-hand side with the left inverse B we get

$$Bb = \begin{bmatrix} 1 \\ -1 \end{bmatrix}$$

- ◆ and also

$$Cb = \begin{bmatrix} 1 \\ -1 \end{bmatrix}$$

Matrix inverses

Right inverses

- ◆ a matrix X that satisfies $AX = I$ is a *right inverse* of A
- ◆ if a right inverse exists, we say that A is *right-invertible*
- ◆ A is right-invertible if and only if A^T is left-invertible:

$$AX = I \iff (AX)^T = I \iff X^T A^T = I$$

- ◆ so we conclude

A is right-invertible if and only if its rows are linearly independent

- ◆ right-invertible matrices are wide or square

Matrix inverses

Solving linear equations with a right inverse

- ◆ suppose A has a right inverse B
- ◆ consider the (square or underdetermined) equations $Ax = b$
- ◆ $x = Bb$ is a solution:

$$Ax = A (Bb) = (AB) b = I b = b$$

- ◆ so $Ax = b$ has a solution for *any* b

Matrix inverses

Inverse

- ◆ if A has a left and a right inverse, they are unique and equal (and we say that A is *invertible*)
- ◆ so A must be square
- ◆ to see this: if $AX = I$, $YA = I$

$$X = IX = (YA)X = Y(AX) = YI = Y$$

- ◆ we denote them by A^{-1} :

$$A^{-1}A = AA^{-1} = I$$

- ◆ inverse of inverse: $(A^{-1})^{-1} = A$

Matrix inverses

Solving square systems of linear equations

- ◆ suppose A is invertible
- ◆ for any b , $Ax = b$ has the unique solution

$$x = A^{-1}b$$

- ◆ matrix generalization of simple scalar equation $ax = b$ having solution $x = (1/a) b$ (for $a \neq 0$)
- ◆ simple-looking formula $x = A^{-1}b$ is basis for many applications

Matrix inverses

Invertible matrices

◆ the following are equivalent for a square matrix A :

- A is invertible
- columns of A are linearly independent
- rows of A are linearly independent
- A has a left inverse
- A has a right inverse

if any of these hold, all others do

Matrix inverses

Examples

- ◆ $I^{-1} = I$
- ◆ if Q is orthogonal, *i.e.*, square with $Q^T Q = I$, then $Q^{-1} = Q^T$
- ◆ 2×2 matrix A is invertible if and only $A_{11}A_{22} \neq A_{12}A_{21}$

$$A^{-1} = \frac{1}{A_{11}A_{22} - A_{12}A_{21}} \begin{bmatrix} A_{22} & -A_{12} \\ -A_{21} & A_{11} \end{bmatrix}$$

- there are similar but much more complicated formulas for larger matrices

Matrix inverses

Non-obvious example

$$A = \begin{bmatrix} 1 & -2 & 3 \\ 0 & 2 & 2 \\ -3 & -4 & -4 \end{bmatrix}$$

◆ A is invertible, with inverse

$$A^{-1} = \frac{1}{30} \begin{bmatrix} 0 & -20 & -10 \\ -6 & 5 & -2 \\ 6 & 10 & 2 \end{bmatrix}$$

◆ verified by checking $AA^{-1} = I$ (or $A^{-1}A = I$)

Matrix inverses

Properties

- ◆ $(AB)^{-1} = B^{-1}A^{-1}$ (provided inverses exist)
- ◆ $(A^T)^{-1} = (A^{-1})^T$ (sometimes denoted A^{-T})
- ◆ negative matrix powers: $(A^{-1})^k$ is denoted A^{-k}
- ◆ with $A^0 = I$, identity $A^k A^l = A^{k+l}$ holds for any integers k, l

Matrix inverses

Triangular matrices

- ◆ lower triangular L with nonzero diagonal entries is invertible
- ◆ so see this, write $Lx = 0$ as

$$\begin{array}{rcl} L_{11}x_1 & = & 0 \\ L_{21}x_1 + L_{22}x_2 & = & 0 \\ & \vdots & \\ L_{n1}x_1 + L_{n2}x_2 + \cdots + L_{n,n-1}x_{n-1} + L_{nn}x_n & = & 0 \end{array}$$

- from first equation, $x_1 = 0$ (since $L_{11} \neq 0$)
- second equation reduces to $L_{22}x_2 = 0$, so $x_2 = 0$ (since $L_{22} \neq 0$)
- and so on

this shows columns of L are linearly independent, so L is invertible

- ◆ upper triangular R with nonzero diagonal entries is invertible

Matrix inverses

Inverse via QR factorization

- ◆ suppose A is square and invertible
- ◆ so its columns are linearly independent
- ◆ so Gram–Schmidt gives QR factorization
 - $A = QR$
 - Q is orthogonal: $Q^T Q = I$
 - R is upper triangular with positive diagonal entries, hence invertible
- ◆ so we have

$$A^{-1} = (QR)^{-1} = R^{-1}Q^{-1} = R^{-1}Q^T$$

Matrix inverses

Back substitution

- ◆ suppose R is upper triangular with nonzero diagonal entries
- ◆ write out $Rx = b$ as

$$\begin{aligned} R_{11}x_1 + R_{12}x_2 + \cdots + R_{1,n-1}x_{n-1} + R_{1n}x_n &= b_1 \\ &\vdots \\ R_{n-1,n-1}x_{n-1} + R_{n-1,n}x_n &= b_{n-1} \\ R_{nn}x_n &= b_n \end{aligned}$$

- ◆ from last equation we get $x_n = b_n / R_{nn}$
- ◆ from 2nd to last equation we get

$$x_{n-1} = (b_{n-1} - R_{n-1,n}x_n) / R_{n-1,n-1}$$

- ◆ continue to get $x_{n-2}, x_{n-3}, \dots, x_1$

Matrix inverses

Back substitution

- ◆ called *back substitution* since we find the variables in reverse order, substituting the already known values of x_i
- ◆ computes $x = R^{-1}b$

Matrix inverses

Solving linear equations via QR factorization

- ◆ assuming A is invertible, let's solve $Ax = b$, *i.e.*, compute $x = A^{-1}b$
- ◆ with QR factorization $A = QR$, we have

$$A^{-1} = (QR)^{-1} = R^{-1}Q^T$$

- ◆ compute $x = R^{-1}(Q^T b)$ by back substitution

Matrix inverses

Solving linear equations via QR factorization

- ◆ given an $n \times n$ invertible matrix A and an n -vector b
 1. *QR factorization*: compute the QR factorization $A = QR$
 2. compute $Q^T b$.
 3. *Back substitution*: Solve the triangular equation $Rx = Q^T b$ using back substitution

Matrix inverses

Polynomial interpolation

- ◆ let's find coefficients of a cubic polynomial

$$p(x) = c_1 + c_2x + c_3x^2 + c_4x^3$$

that satisfies

$$p(-1.1) = b_1, \quad p(-0.4) = b_2, \quad p(0.1) = b_3, \quad p(0.8) = b_4$$

- ◆ write as $Ac = b$, with

$$A = \begin{bmatrix} 1 & -1.1 & (-1.1)^2 & (-1.1)^3 \\ 1 & -0.4 & (-0.4)^2 & (-0.4)^3 \\ 1 & 0.1 & (0.1)^2 & (0.1)^3 \\ 1 & 0.8 & (0.8)^2 & (0.8)^3 \end{bmatrix}$$

Matrix inverses

Polynomial interpolation

- ◆ (unique) coefficients given by $c = A^{-1}b$, with

$$A^{-1} = \begin{bmatrix} -0.0201 & 0.2095 & 0.8381 & -0.0276 \\ 0.1754 & -2.1667 & 1.8095 & 0.1817 \\ 0.3133 & 0.4762 & -1.6667 & 0.8772 \\ -0.6266 & 2.381 & -2.381 & 0.6266 \end{bmatrix}$$

- ◆ so, *e.g.*, c_1 is not very sensitive to b_1 or b_4

Matrix inverses

Invertibility of Gram matrix

- ◆ A has linearly independent columns if and only if $A^T A$ is invertible
- ◆ to see this, we'll show that $Ax = 0 \Leftrightarrow A^T Ax = 0$
- ◆ \Rightarrow : if $Ax = 0$ then $(A^T A)x = A^T(Ax) = A^T 0 = 0$
- ◆ \Leftarrow : if $(A^T A)x = 0$ then

$$0 = x^T (A^T A)x = (Ax)^T (Ax) = \|Ax\|^2 = 0$$

so $Ax = 0$. We have $x = 0$ since the columns of A are linear independent

Matrix inverses

Pseudo-inverse of tall matrix

- ◆ the *pseudo-inverse* of A with independent columns is

$$A^\dagger = (A^T A)^{-1} A^T$$

- ◆ it is a left inverse of A :

$$A^\dagger A = (A^T A)^{-1} A^T A = (A^T A)^{-1} (A^T A) = I$$

- ◆ reduces to A^{-1} when A is square:

$$A^\dagger = (A^T A)^{-1} A^T = A^{-1} A^{-T} A^T = A^{-1} I = A^{-1}$$

Matrix inverses

Pseudo-inverse of wide matrix

- ◆ if A is wide, with linearly independent rows, AA^T is invertible
- ◆ pseudo-inverse is defined as

$$A^\dagger = A^T (AA^T)^{-1}$$

- ◆ A^\dagger is a right inverse of A :

$$AA^\dagger = AA^T (AA^T)^{-1} = I$$

- ◆ reduces to A^{-1} when A is square:

$$A^T (AA^T)^{-1} = A^T A^{-T} A^{-1} = A^{-1}$$

Matrix inverses

Pseudo-inverse via QR factorization

◆ suppose A has linearly independent columns, $A = QR$

◆ then $A^T A = (QR)^T (QR) = R^T Q^T Q R = R^T R$

◆ so

$$A^\dagger = (A^T A)^{-1} A^T = (R^T R)^{-1} (QR)^T = R^{-1} R^{-T} R^T Q^T = R^{-1} Q^T$$

◆ can compute A^\dagger using back substitution on columns of Q^T

◆ for A with linearly independent rows, $A^\dagger = QR^{-T}$
